Signals & Related Equipment

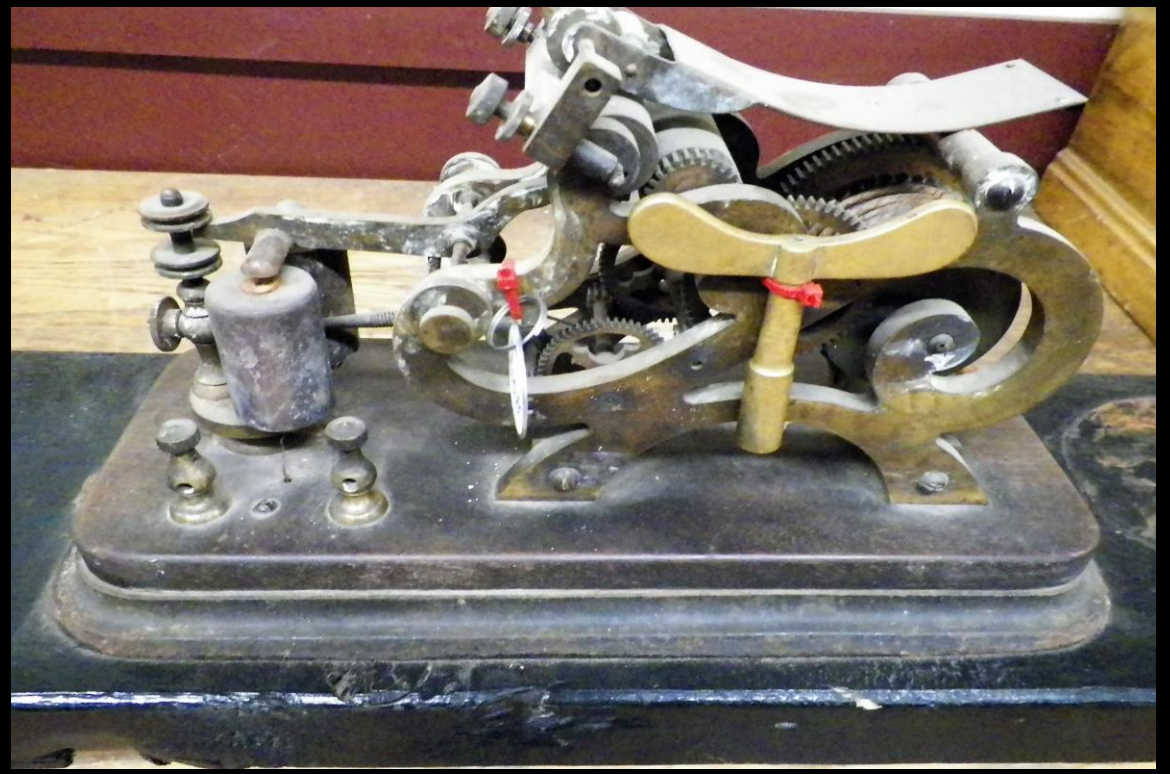
Hardware Collection

Train Signal & Equipment

- During the early years of railroading, methods had to be devised to ensure that two trains did not meet at the same time on the same section of track.
- This was initially accomplished through the use of timetables and train orders.
- Block Signal systems were developed, which indicated to the locomotive engineer whether or not a train was head in the next block of track.
- These signals were set manually until the track circuit was developed, which sensed the presence of a train in the block and set the signals automatically.
- The track circuit was designed to be fail-safe, so that the battery or any wire connections were to fail or if a rail was broken, a clear signal would be displayed.
- Insulated joints were used to define the limits of the block.
- Various types of track circuits are utilized in automatic traffic control device installations at highway-rail grade crossings.

Morse Recording Register with Brass Key Circa 1890's

Conn River Line 38 ¼"x 7"x 5..5"



Boston & Maine Railroad Historical Society - Railroad Telegraph Display

Donation by; Donald F. Hodge

Resonator Box w/ Sounder

The Sounder is in a Candlestick base Resonator.

The Resonator box is mounted on a metal candlestick phone style base.

The Sounder is a Telegraph Instrument that allowed an operator to receive and interpret an incoming message by the Sounder.

Glass Insulators

- Glass Insulators were first manufactured in quantity in the 1800's when the first telegraph and telephone circuits were put in place. A way was needed to prevent the telegraph signal from draining into the earth wherever the wire touched a sold object.
- Insulators were invented to fulfill this need.
- There are hundreds of different styles and color insulators today.
- Many of the older pieces were made from glass or porcelain.
- Smaller insulators were used on telephone and telegraph circuits, and larger insulators were made for electrical (power supply) wires.
- Generally speaking, the higher the voltage in the power lines, the larger the insulator holding those lines has to be. This is because electricity can actually " jump" over a fairly long path if the voltage is high enough.
- Insulators with wide "umbrella" disk and wide lower skirts (the flared-out part on the insulator's bottom) are designed to keep the distance between the wire and the pole as long as possible, so that this "jumping" or arcing doesn't happen.

Glass Signal Battery Jar

Fitz William New Hampshire

Battery Jars & Covers: Cylindrical Type / Rectangular Type

The following description of how the battery works:

The electrolyte is derived from a blue vitriol and water solution.

The blue vitriol must completely cover the copper element, and sufficient water must be added to cover the zinc element.

A teaspoonful of sulphuric acid is added to this solution to give the best results.

In order to prevent creeping of the electrolytic salts, the top of the jar is generally dipped into hot paraffiny. Best results are obtained by pouring a layer of pure mineral oil over the top of the electrolyte, because it prevents evaporation as well as the creeping of salts.

To put the battery into service after these steps have been taken, it is necessary only to place the cell an a short circuit for about 24 hours.

Donation by; Robert Grodzicki

Wooden Whistle Post

Whistles are just as essential in the operation of a railroad as are block signals, and other safety devices. Each different series of toots carries its on special message of warning or instruction.

Here is the "whistle language" used by the B an M:

"------"means a long toot; "0" means a short one.

------ ------ 0 0 Approaching crossing (last short toot sounds just as crossing is reached)

---------- 0 0 0 When train stops on main line, engineer instructs flagman to protect rear end of train.

------ ------ ------ ------ Train ready to proceed. Engineer calls in flagman from West or South.

------ ------ ------ ------ ------ Train ready to proceed. Engineer calls in flagman from East or North.

0 0 0 When train is stopped, engineer is going back. When train is running, engineer acknowledges signal from conductor to stop at next station.

---------- 0 0 0 when train is running, alarm for fire or livestock on the right-of-way. Signal is given two or three times as train passes fire or livestock, and again on reaching next station or section crew.

---------- Approaching junction, or mail crane where train picks up mail bag "on the fly", or for warning.

0 0 0 0 0 0 0 (succession) Alarm for persons or livestock on the track.

Donation by; Paul T. Kosciolek

Signaling: Central Traffic Control

- Central Traffic Control (CTC)
  Controls the movement of all trains over the many miles of track outlined on the board.
- The system consists of a centralized train Despatcher’s Office that controls railroad interlocking's and traffic flows in portions of the rail system designated as CTC territory.
- The Despatcher establishes a rout for trains many miles away by depressing the “Bottom Levers” which controls the routing signals.
- The “Top Levers” which control switches at interlocking, and by radio and telephone communication.
- Flip switches ignite the switch Snow Melter's.
- This Central Traffic Control console governs train movement on dingle and double track.
- Several similar consoles control different segments of the Boston & Maine Railroad System.

- The three B&MRR Central Traffic Control boards came from North Billerica, Ma.
- CTC controls railroad interlocking's and traffic flows from Rigby, ME to Dover, N.H.

High vs Low or Dwarf Signals

High Signals:

Typically can give authorization for a train to proceed at the maximum allowable speed as given on the Timetable or in the Rules Book.

Dwarf Signals:

Are usually limited to medium or slow movements.

Limited Speed:

A speed not exceeding 45 miles per hour.

Passenger Trains 45 MPH / Freight Trains 40 MPH

Medium Speed:

A speed not exceeding 30 miles per hour.

Automatic and Approach Signal

Automatic Block – Block aspects convey basic track occupancy information and advise the engine (operator) which of the basic signal rules (common to all railroads) he/she is to follow in the operation of his/her train at any point on the railway line.

These include clear, advance Approach, Approach which instruct the engineer to “expect no stop”, “expect stop at second signal” and “expect stop at next signal” respectively.

Approach at Speed – When a train needs to be told to slow down due to dynamic conditions an “Approach Speed” aspect is used. These inform the engineer to slow to a prescribed speed by the next signal.

The most common reason for this is that the train is to take a diverging, or non-Normal speed route at the next interlocking.

Signals of this type include Approach Medium, Approach Limited, Approach Slow and Approach Diverging.

General Railway Signal Co.

Color-Light Signals

Consist of three bulbs shining through 3 lenses, or “Roundels,” one each Red, Yellow and Green. Typically, the lights are grounded vertically with green at the top, exactly opposite of the highway traffic signals that protect road intersections.

A need to protect signals in Subway-Tunnels led to the development of Color-Light Signals, in the first decade of this century.

Donation by; Michael Pace

Searchlight Basics

SA Searchlight Signals released for production in 1927.

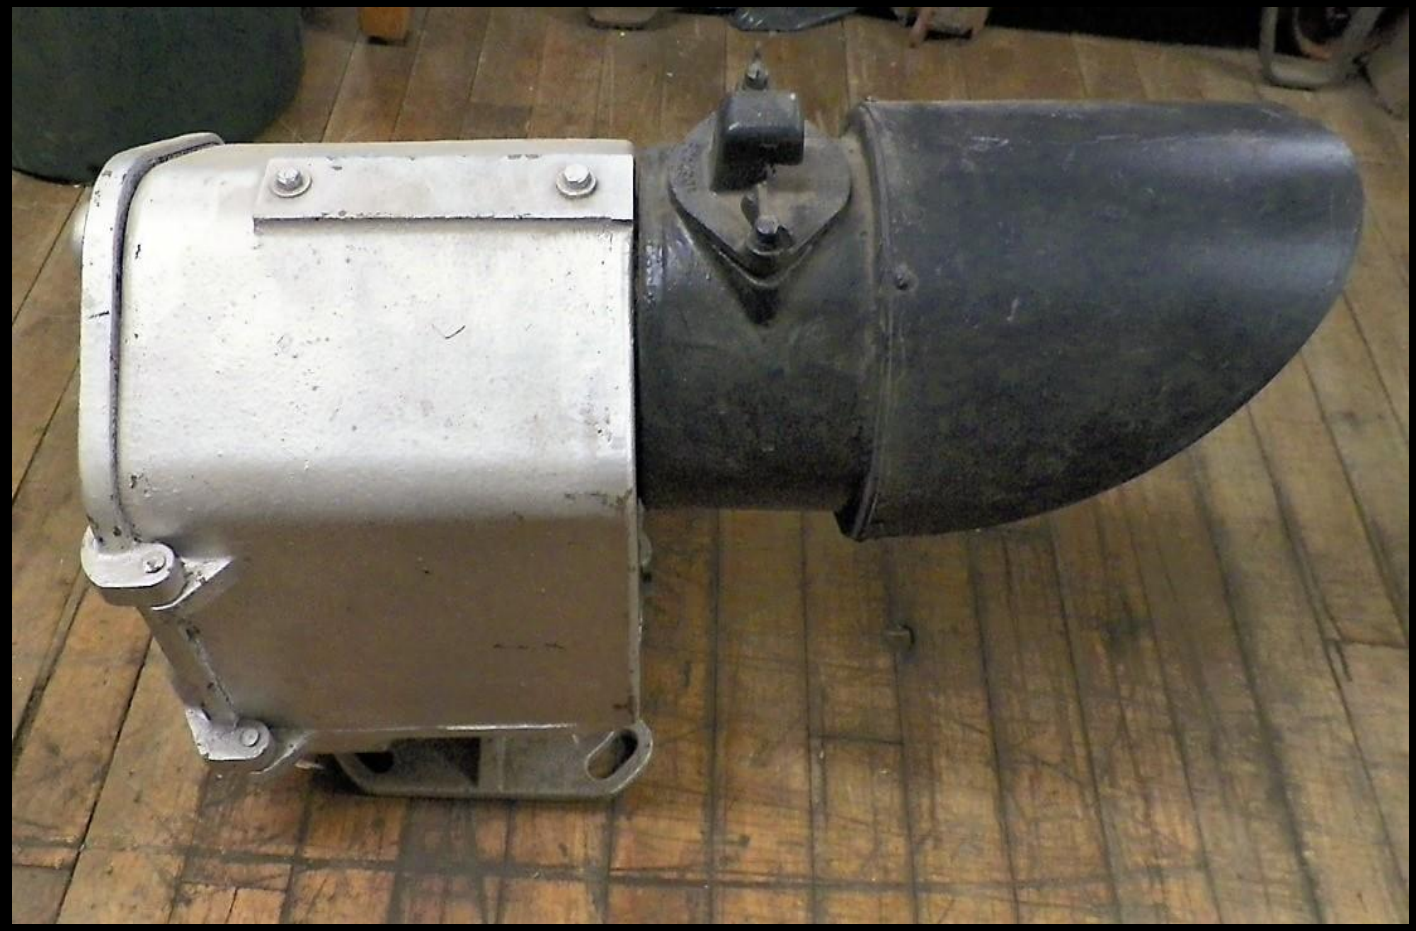
Over 70,000 SA Searchlight units have been produced to date.

Searchlight Signals have only one set of lenses and a single light source.

The searchlight signal is one of the few signals that uses a reflector.

The reflector is elliptical in shape, and the blub is put at the focus point of the reflector.

The placement of the blub is positioned so that the light beam is focused to another focal point before leaving the lamp assembly.



B&MRR Dwarf Semaphore Signal

B&MRR 2 Position Dwarf Semaphore Signal:

Dwarf signals normally control movements from a siding to a mainline or from mainline to a siding or from mainline to mainline.

The 2 position dwarf only tells you that the points are set for the move, they can be placed to “proceed” when the track ahead is occupied.

They are very similar in appearance to a 3 position dwarf signal.

In later years some 2 position dwarfs were light signals, in this form they were indistinguishable from a 3 position dwarf.

The big difference between a 2 and 3 position dwarf is that a 2 position dwarf showing a green light, “proceed” did not imply the track was clear, a 3 position dwarf displaying a green light “clear low speed” tells the driver that the track is clear to the next signal.

The Dwarf Signal was from:
Hale Street Interlocking Lowell, MA. Located North of Hale Street Bridge on the west-side. Was removed when the Hale Street Tower was closed in the 1940’s, a new Lowell Tower was built.

Donation by; Donald S. Robinson

United Switch & Signal Co.

Signal Indicator

This is a US&S Trackside Block Indicator.
They were mounted on a short pole and allowed track crews or train crews stopped at a siding to see the signal indicator.

By default a semaphore is in the “Stop” position and drops when voltage is applied (very low voltage).

Donor; Anonymous

Train Order Semaphore Signal Boards

- Train Order Signals:
- In North America, Semaphores were employed as train order signals, with the purpose of indicating to engineers whether they should stop to receive a telegraph order.
- It was common for train order signals to point the arm straight down to indicate “Procced” train order signals were typically located at the station building, with a tall common post mounted signal arms falling in opposing directions.

- MECRR Train Order Signal Boards

Combined Stop and Distant Signal Semaphores

- Combined Stop & Distant Signal:
- Where signals are closely spaced, a stop signal and a distant signal can be mounted on the same post.
- The distant signal is always the lower of the two.
- The two signals are “Slotted” so that the distant signal can only clear if the stop signal is clear.
- Both signals display a light at night, which means that the danger indication appears as red over yellow.

Donation by; Joanne Reynolds

GRAY BOSTON
Train Order Lamps

Signal Lamp was either a Train Order Signal or a Semaphore Lamp. It was mounted on a signal pole to notify on coming trains to pick up orders at the next stop.

It is electrified and appears to be Circa 1920’-30’s.

Train Order Fork's

Train Order provides the means to deal with changes in operating conditions as they rise. A paper order was placed in the train Order Fork or Hoop, either held by the operator or mounted at trackside. The Yellow Order Fork's are 75" Long and 54" long.
